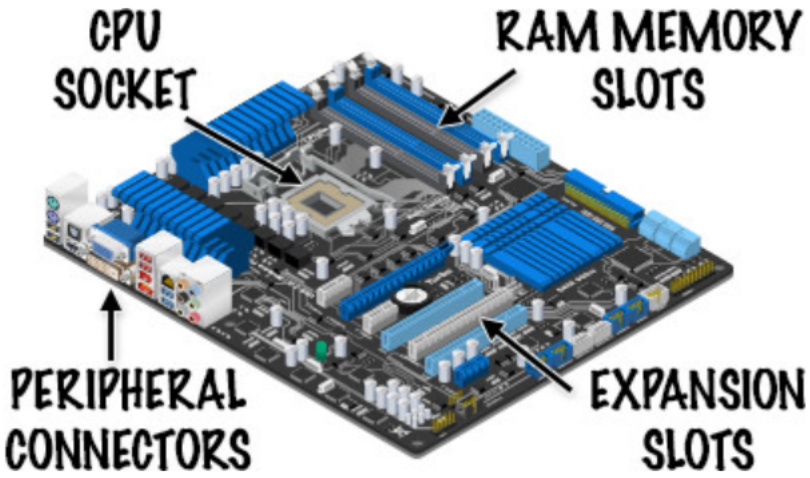
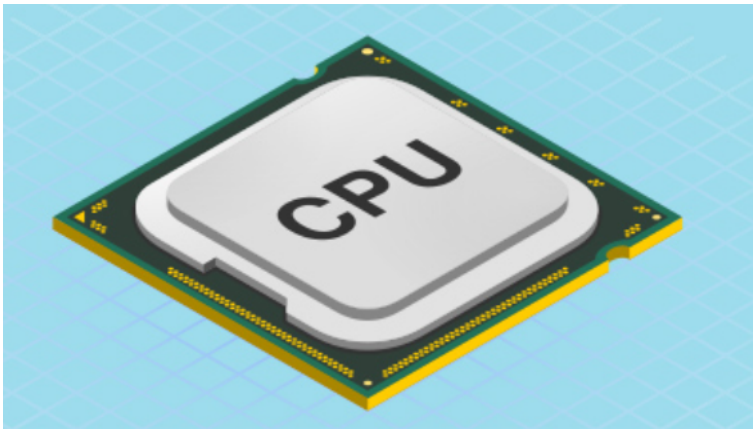
Motherboard

An example of a motherboard and some of its main parts is below:



A motherboard is a printed circuit board (PCB) that holds the main components of a computer system. So things like the CPU, RAM & Graphics/Sound Cards connect and communicate through the motherboard.

Central Processing Unit (CPU)

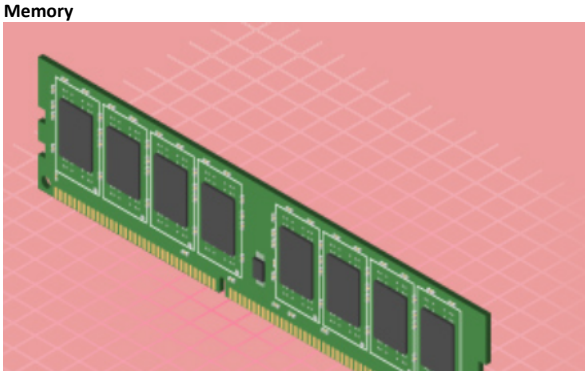


This is responsible for performing all of the instructions that are given by the programs you run on your computer. It handles inputs, process them and delivers outputs.

Three key components of the CPU are:

- Arithmetic Logic Unit (ALU)
- Control Unit
- Registers

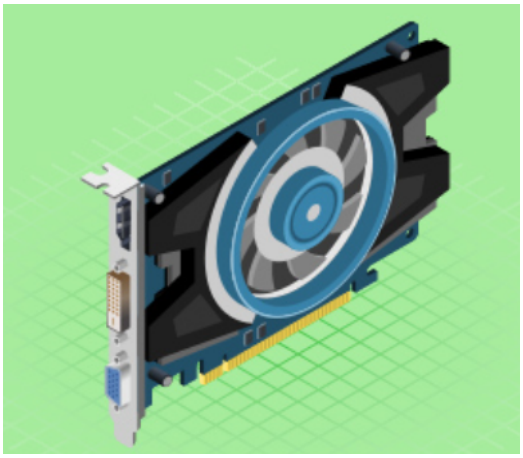
Memory



Memory is used to store information within the computer system.

There are three main types of memory:
- Random Access Memory
- Read Only Memory
- Flash Memory

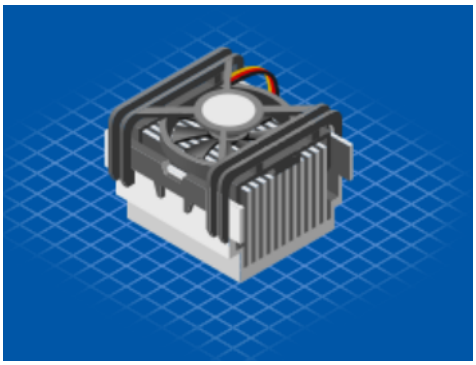
Graphics/Sound Card



Sometimes known as a video card, the graphics card produces an image to display via an output device, such as a monitor.

A sound card is used to produce audio that can then be outputted via dvices such as speakers and headphones.

Heat dispersal system



Computers produce heat which can damage the computers components if left unchecked. We use heat dispersal systems to reduce the heat and prevent it causing damage.

The main two heat dispersal systems are:
- Heat Sink
- Fan

Storage Device

A component of a computer system that is used to store data permenantly, even after the PC is switched off. We use this to store the operating systems, applications and our document files.

The most common forms are:

- Magnetic
- Optical
- Solid State
